Chapter 1

Introduction

1.1 ElSpec

ELSPEC is a MATLAB toolbox for estimating differential energy flux of precipitating electrons from field-aligned EISCAT incoherent scatter radar observations of ionospheric electron density. The ELSPEC input data are analysis results from the standard EISCAT data analysis tool, GUISDAP. The input data may be GUISDAP raw densities, GUISDAP fit results, or both. Electron density profiles from other than field-aligned directions are automatically excluded from the analysis. Several different models of ion production, recombination, and ion composition are available. Also time-resolution and energy grid points can be selected by the user, the former within the limits set by EISCAT experiment design.

ELSPEC is an upgraded version of the electron energy spectrum estimation technique developed by Björn Gustavsson, which was used in (*Dahlgren et al.*, 2011). The upgraded technique and validation results are published in (*Virtanen et al.*, 2018)

1.2 System requirements

ELSPEC has been run on Linux with MATLAB2021b and earlier versions. Other reasonably recent MATLAB versions and other operating system will probably work as well.

ELSPEC uses the MATLAB implementations of the NRLMSISE-00 model (atmosnrlmsise00) and IGRF (igrfmagm) in the Aerospace toolbox. This version of ELSPEC cannot be used without the Aerospace toolbox.

1.3 Installation

ELSPEC is distributed as a MATLAB toolbox. Add full path to the 'ELSPEC' directory in your MATLAB search path or, if you received the package as an .mltbx-file, install it using the MATLAB toolbox installer (a double-click is typically enough).

1.4 Help

Standard MATLAB help messages are available at least for the user interface functions. Full command references for the main inversion and plotting routines are given in Appendix A of this document.

1.5 Reference

In published scientific works using ELSPEC, please refer to the paper:

Chapter 2

Electron energy spectrum estimation

The electron energy spectrum inversion is shortly outlined in this chapter. See (*Virtanen et al.*, 2018, and references therein) for details.

2.1 Electron precipitation and ion production

Energetic electrons precipitating to the ionosphere cause collisional ionization. If plasma convection and photoionization can be neglected, the electron gas will follow the continuity equation

$$\frac{\partial N}{\partial t} = Q + \alpha N^2, \tag{2.1}$$

where N is the electron number density, t is time and Q is electron production rate per unit volume.

The ion production rate depends on composition of the neutral atmosphere and the differential number flux of the precipitating electrons. If the neutral atmosphere is known, Q can be calculated for arbitrary electron fluxes and altitudes. Similarly, if the ion composition is known, the effective recombination coefficient α can be calculated.

Incoherent scatter radars can observe electron density as function of time and altitude along a geomagnetic field-line. At night the assumptions of negligible photoionization and plasma convection are reasonable in the E region. Because the ion production rate can be expressed as a function of the differential number flux I, $Q = Q(I(t))$, the differential number flux can be inverted from the incoherent scatter radar data.

2.2 ELSPEC implementation

Key points of the ELSPEC inversion are *analytic integration of the electron continuity equation*, *fits with multiple models* of the spectrum shape, and *model selection* by means of the Akaike information criterion. These are shortly outlined below.

2.2.1 Integration of the electron continuity equation

Input data to ELSPEC are vectors of electron density at discrete height-gates h_i, sampled at times t_j,

$$N_j = \begin{pmatrix} N_{j,1} \\ N_{j,2} \\ \vdots \\ N_{j,H} \end{pmatrix}, \tag{2.2}$$

where H is the number of height gates.

Ion production rate in each gate are calculated as matrix product

$$Q_j = AI_j, \tag{2.3}$$

where Q_j is a vector of ion production rates, elements of the matrix A are calculated using an ion production model, and I_j is the differential number flux. In a similar manner, the effective recombination coefficients in each height gate are collected in a vector

$$\alpha_j = \begin{pmatrix} \alpha_{j,1} \\ \alpha_{j,2} \\ \vdots \\ \alpha_{j,H} \end{pmatrix}. \tag{2.4}$$

A key point in the ELSPEC implementation is that the time-derivative of electron density $\partial N / \partial t$ is not explicitly calculated from data, but the software makes an iterative search to find the differential number flux I that leads to best match between the observed electron density and the analytic solution from Equation (2.1). Electron density as function of time, as solved from (2.1), is

$$n(t) = \frac{n(t_{j-1}) + \sqrt{Q_j/\alpha_j} \tanh\left(\sqrt{\alpha_j Q_j} t\right)}{1 + \sqrt{\alpha_k Q_j} n(t_{j-1}) \tanh\left(\sqrt{\alpha_j Q_j} t\right)} \quad , t_{j-1} \le t \le t_j. \tag{2.5}$$

Here $n(t)$ is the electron density and $n(t_{j-1})$ is the density at beginning of the current time step. Because the radar observations are averages over a time step,

the model values, which should match with the observed densities, are integrated from (2.5),

$$\mathbf{n}_k = \frac{1}{\alpha_k \Delta t} \left(\log \left(\frac{\mathbf{n}(t_{k-1}) \sqrt{\alpha_k/\mathbf{Q}_k} \tanh\left(\sqrt{\alpha_k \mathbf{Q}_k} \Delta t\right) + 1}{\tanh\left(\sqrt{\alpha_k \mathbf{Q}_k} \Delta t\right) + 1} \right) + \sqrt{\alpha_k \mathbf{Q}_k} \Delta t \right). \quad (2.6)$$

2.2.2 Spectrum models

The inverse problem in electron energy spectrum estimation is ill-posed in general, because large energy interval needs to be covered with rather high resolution, but typically only some tens of electron density observations are available for each time step. Regularizing information is thus needed, and this information is included in the form of parametric spectrum shape models in ELSPEC.

There is a variety of models one could potentially use. For example, Maxwellian and κ distributions, as well as narrow- and wide-band accelerated spectra are observed by satellites above and within the ionosphere. The original implementation in *Dahlgren et al.* (2011) used an exponential of a spline expansion, with both the spline node locations and their amplitudes determined in the inversion.

ELSPEC uses a slightly different polynomial model, because the model of *Dahlgren et al.* (2011) reduces to a polynomial when number of spline nodes is small, which is almost always the case, and the polynomials are technically somewhat easier to control. The polynomial model is of the form

$$I = E \exp\left(\sum_{l=0}^{L} P_L(l) E^l \right), \quad (2.7)$$

where P_L is a vector of $L + 1$ polynomial coefficients, which are the unknowns in the inversion. The vector E is the selected energy grid. The model can produce exact Maxwellian fluxes, as well as slightly distorted ones with $L = 1$, and more complex shapes, such as κ distributions, with higher L.

2.2.3 Model selection

On each time-step, ELSPEC runs a separate fit for each spectrum shape model with $L = 1, 2, \ldots, N_{max}$, where N_{max} is typically between 5 and 10. The optimal one, which is then selected as the final estimate of the differential number flux, is then selected by means of the Akaike information criterion (e.g. *Burnham and Anderson*, 2002).

2.2.4 Error estimation

Error estimation in ELSPEC is somewhat complicated, because the error in the modeled electron density in beginning of the integration must be taken into account. An error estimation based on an assumption of Gaussian error distributions and numerical derivatives of linearized theory in vicinity of the iteration convergence point is implemented.

2.2.5 Derived parameters

Several derived parameters and their error estimates are calculated from the differential number flux estimates I_j and their covariances.

Differential energy flux is calculated as a product of the differential number flux and the known energy grid values.

Upward field aligned current carried by the precipitating electrons is integrated from the differential number flux. However, this estimate might not reflect the true field-aligned current, because ELSPEC cannot see either upward moving electrons or low-energy electrons (typically below 1 keV), whose contribution to the net current may be significant.

Auroral power (integral energy flux) of the precipitation is integrated from the differential energy flux. These estimates are accurate, because contribution of the low-energy electrons is very small. The auroral power estimates have been found to be very accurate even if the shape of the differential energy flux is not.

Chapter 3

ELSPEC in practice

The user interface to the ELSPEC inversion is the function `ElSpec`, which can be called with various optional parameters. The parameters, their default values, and examples of their use are listed in Appendix A. This chapter explains most important parts of the analysis in more detail.

3.1 The simplest example

The simplest, but typically suboptimal way to use ELSPEC is to use standard fitted GUISDAP analysis results as input. Because the default setting are for EISCAT UHF beata experiment, more or less reasonable results will be produced if one cd's to a GUISDAP output directory of any field-aligned (CP1) UHF beata experiment and runs the command

```
>> ElSpecOut = ElSpec('fitdir','.');
```

The software will print its settings, including the output file name. The output file contains a MATLAB struct 'ElSpecOut', where all settings and the inversion results are stored. The same structure is returned by the function when the analysis is complete. The results can be visualized with the function 'ElSpecPlot'. In the simplest case a plot is produced with the command

```
>> ElSpecPlot(ElSpecOut);
```

3.2 Input data

ELSPEC can use two kinds of EISCAT data as input, 'normal' GUISDAP fit results and high-resolution 'raw densities' from two specific experiments, UHF beata and arc1. The GUISDAP options for calculating the sufficient raw densities

are given in Section 3.3. The different input options are explained in the following three subsections.

3.2.1 Both ppdir and fitdir are defined

If both `ppdir` and `fitdir` are given in the `ElSpec` function call, the electron density data are read from raw electron densities in `ppdir`. Electron temperatures are extracted from the fit results in `fitdir`.

In this case the `tres` argument is effective and has two alternatives. `dump` means that the raw densities from EISCAT data dumps are integrated together. Standard deviation of the electron density is calculated as a sample average over all raw density profiles in a data dump. `best` means that the original, best available time resolution is maintained. The same standard deviations are copied for all raw density profiles in each EISCAT data dump.

This combination is currently available only for EISCAT UHF 'beata' and 'arc1' experiments.

3.2.2 Only fitdir is defined

If only `fitdir` is defined but `ppdir` is not, ELSPEC reads both electron densities and electron temperatures from the same GUISDAP fit files. This option works with all EISCAT experiments, because the fit results are in a standard format.

Notice that temperature estimation is typically not possible with very high time resolutions. If GUISDAP is set to fit only electron densities, the temperatures in GUISDAP output files will be from the IRI model.

3.2.3 Only ppdir is defined

If only `ppdir` is defined, ELSPEC uses the raw electron densities in `ppdir` and takes the electron temperature from a model. Depending on the selected ion recombination model, this model is either IRI or MSIS. In the latter case, electron temperature is assumed to be equal to the neutral temperature.

The electron temperature is taken from the IRI model if it is needed for the recombination model. Recombination models (`recombmodel`) using IRI are `'Rees'`, `'SheehanGr'` and `'SheehanEx'` (the last one is probably not useful in practice).

This option is available only for EISCAT UHF 'beata' and 'arc1' experiments.

3.3 Running the GUISDAP analysis

GUISDAP default options are sufficient for calculating the normal fit results in `fitdir`. However, one should carefully calibrate the data, because the energy spectrum is a nonlinear function of the density, and calibration errors may have significant, nontrivial effects to the spectrum estimates.

In order to calculate the raw electron density estimates in `ppdir`, one should use the GUISDAP settings

```
analysis_ppshortlags=1
analysis_pponly=1
a_satch.do=0
```

The last one disables the GUISDAP satellite echo detection, which may sometimes cause problems with very high time resolutions. The analysis can be run also with the satellite check, but ELSPEC cannot read in data files with data points missing due to satellite echo detections, and such files have to be manually removed. In addition, the analysis time-resolution should be matched with the EISCAT dump length, which is 4 s for UHF arc1 and 5 s for UHF beata. With these options the analysis does not produce the standard fitted parameters at all, but stores only the raw densities with highest available resolutions. ELSPEC provides input routines for reading the experiment-specific GUISDAP outputs for UHF beata and arc1.

Power calibration is most practical for the standard fit results. The 'magic constant' estimated with the standard fit can (and should) be used also for the raw density fits.

3.4 Ion production models

ELSPEC allows the user to select between two alternative ion production models. The first implementation used in *Dahlgren et al.* (2011) used an ion production model by (*Sergienko and Ivanov*, 1993), which can be selected with the `ionomodel` parameter. The default model is from a more recent work by (*Fang et al.*, 2010).

3.5 Ion recombination models

The effective recombination coefficient α may be an issue in the energy spectrum inversion, because the coefficient depends on two poorly known things, the ion composition and the recombination coefficients of individual ion species.

The default choice is to use recombination speeds for ions in vibrational ground state from laboratory measurements (*Sheehan and St-Maurice*, 2004) and assume

that only NO$^+$ and O$_2^+$ ions, whose abundances are taken from IRI, are present. The recombination coefficients are different from e.g. the widely used values by *Rees* (1989), who did not provide different values for the vibrationally excited states. Although there is no practical means to monitor the vibrational state of the molecular ions, the excited states are short-lived in comparison to the ion recombination times, and wast majority of the ions should be in ground state.

The IRI compositions are known to be suboptimal, because the collisional ionization produces large amounts of O$_2^+$, whose contribution varies rapidly along changes in the precipitation flux. The incorrect compositions have been found to cause up to 30 % error in the net power flux estimates. In order to provide simpler models, which may be equally good in practice, the package contains options for assuming pure NO$^+$ or pure O_2^+ ionospheres.

Altogether nine different options for the ion recombination model are currently available. These are listed in Appendix A.

3.6 Time resolution

ELSPEC contains a build-in system for controlling the time-resolution according to ionospheric conditions. When electron density is high and recombination fast, the time resolution will automatically drop to the shortest one allowed by the data. When the recombination is slow the user can allow ElSpec to fit to longer periods fo data. The time resolution is determined for each time step and altitude separately, meaning that e.g. low densities at the upper E region may be analyzed with a coarser time resolution than the E region peak.

The adaptation to the recombination time is built in the system and cannot be directly accessed by the user. The adaptation is based on scaling the electron density variances according to the recombination time-scale, as explained in *Virtanen et al.* (2018).

However, the user can control the maximum amount of data used in each fit with the `ninteg` parameter. If this parameter is set to one, the adaptation is disabled and data from exactly one time step is always used.

Chapter 4

Examples

This chapter provides some practical examples of using ELSPEC.

4.1 UHF beata with raw densities

Figure 4.1: Left: A GUISDAP GUI window with settings for a fit, which will produce the electron temperature estimates for ELSPEC. Right: A GUISDAP GUI window with setting for a fit of the raw electron densities.

A default ELSPEC use case is inversion of EISCAT UHF beata data, using both GUISDAP fits of all plasma parameters and raw electron densities.

First of all, a 'normal' GUISDAP fit with a rather coarse time resolution is needed. 60 s is typically enough for reasonable temperature estimation. The default height limits for temperature estimation are typically a bit high, and better electron temperature and density estimates can be gained if ion temperature is fitted above 80 km and the electron-to-ion temperature ratio above 103 km. The limits can be set with the GUISDAP `fit_altitude` option. An example of a GUISDAP GUI is given on the left panel of Figure 4.1.

After running the analysis, one should carefully calibrate the data, using either plasma lines or comparisons with the EISCAT dynasonde. For example, the dynasonde calibration can be done with the standard GUISDAP function `calib_ne`. Notice that ELSPEC is typically used in conditions, where E region may have strong ionization but the F region is empty, so it may be better to calibrate against the E region peak densities. Also, the dynasonde calibration should be made with a time period where the ionosphere is more or less stable. Another option is to use the plasma line data in beata, which is often available because the electron precipitation heats the electron gas. The plasma lines have the benefit that they are from the very same volume with the ion line data.

The calibration will suggest a 'Magic constant'. If the value is different from that used in the original analysis, the analysis should be run again with the correct magic constant. The calibration should be checked again after the second analysis run, but is typically OK at this point. If not, one more analysis run might be needed.

When the data are correctly calibrated, high-resolution raw densities should be calculated from the same data. This is done by means of setting

```
analysis_ppshortlags=1
analysis_pponly=1
a_satch.do=0
```

in GUISDAP, and selecting a time resolution that matches with the EISCAT data dump length. In UHF beata the resolution is 5 s. An example of a GUISDAP GUI with sufficient settings is given on the right in Figure 4.1.

After the GUISDAP analysis, we will have the 60 s fitted parameters and the 5 s raw densities in separate directories. In this case the directories are `2015-02-16_beata_60s@uhfa` and `2015-02-16_beata_5_rawNe@uhfa`. Because the `ElSpec` defaults are for the UHF beata experiment, we can start the inversion by means of providing only the data directories,

```
>> out=ElSpec('ppdir','2015-02-16_beata_5_rawNe@uhfa','fitdir','2015-02-16_beata_60@uhfa');
```

ELSPEC will then print the license information[1] and its settings. The listing is worth checking, especially when analyzing other EISCAT experiments than the

---

[1]Only on the first call in each MATLAB session

default beata, to be sure that all default parameters match with the experiment at hand. `ElSpec` reads all input data at once, which may take some time. When all data are read the result file name is printed, and information about each time step is printed while the inversion proceeds. An example of the output is given below.

```
>> out = ElSpec('ppdir','2015-02-16_beata_5_rawNe@uhfa','fitdir','2015-02-16_beata_60@uhfa')

With the default settings ELSPEC will regularly update a plot of the inversions results, and will leave a plot of the final results open when the analysis is finished. The default axis limits used in this plot may not be the optimal ones. In this case

we adjust the axis limits with

```
>> ElSpecPlot(out,'plim',[0 10],'faclim',[0 5],'elim',[1 20]);
```

The plot produced with this command is shown in Figure 4.2. The top panel is the observed raw electron density, followed by the density modeled in the inversion, the inverted differential energy flux, the upward field-aligned current, and the net energy flux. The bottom panel is χ^2 of the fit.

Figure 4.2 shows a relatively good match between the observed and modeled densities, but also reveals one key issue in the inversion. Clearly visible mismatch between the model and the observation is seen during sudden decreases in electron density around 23:11, 23:15, 23:28, etc., where the ELSPEC recombination model does not allow the electrons to recombine as fast as the density decreases in the observed data. These issues are possibly related to ion convection – the plasma may have moved out of the radar beam instead of recombining within the beam.

4.2 UHF beata with a steady state model

The steady state assumption, i.e. the assumption that ion production and recombination are in balance during an analysis time step, is widely used in electron energy spectrum inversion. This option can be selected with the `integtype` option of ELSPEC. The same beata data can be analyzed with the steady state assumption using the command

```
out=ElSpec('ppdir','2015-02-16_beata_5_rawNe@uhfa','fitdir', ...
           '2015-02-16_beata_60@uhfa','integtype','equilibrium');
```

Result of this inversion shown in Figure 4.3. A clear difference to the result with time dependet model in Figure 4.2 is that the issue with rapidly decreasing electron densities is not visible. The steady state model finds a precipitation, which would lead to the observed density profile if the energy spectrum remained unchanged for a long period of time. Individual time steps are thus completely independent and the analysis has no problem to adjust to arbitrarily large changes in the electron density. However, the steady state assumption is implicitly wrong and the smoother result is by no means better than the time dependent model – the simplistic steady state model simply hides the issue.

4.3 A fast inversion with fitted data

A simple way to create quicklook plots that give a rough idea of the energy spectrum characteristics is to run the inversion with standard GUISDAP fit results alone. Such an inversion is very fast to run and does not require additional GUISDAP runs on top of a routine parameter fit.

The same data that was used in the two previous examples can be inverted in this way using the command

```
out=ElSpec('fitdir','2015-02-16_beata_60@uhfa','integtype','equilibrium','ninteg',1);
```

Figure 4.4 shows this inversion results. All fine details are missing, because they are averaged out in the 60 s GUISDAP fit. However, the main characteristics of the spectra are roughly still there. Also the estimates of the field-aligned current and the net power flux are reasonably close to the values from the higher resolution inversions. A clear difference to the previous examples are the χ^2 estimates, which are much larger. This is possibly caused by inaccuracies in GUISDAP error estimation, but the actual cause has not been studied in detail. Also the default height resolution of the GUISDAP fit is slightly too coarse for ELSPEC, and may have affected the results.
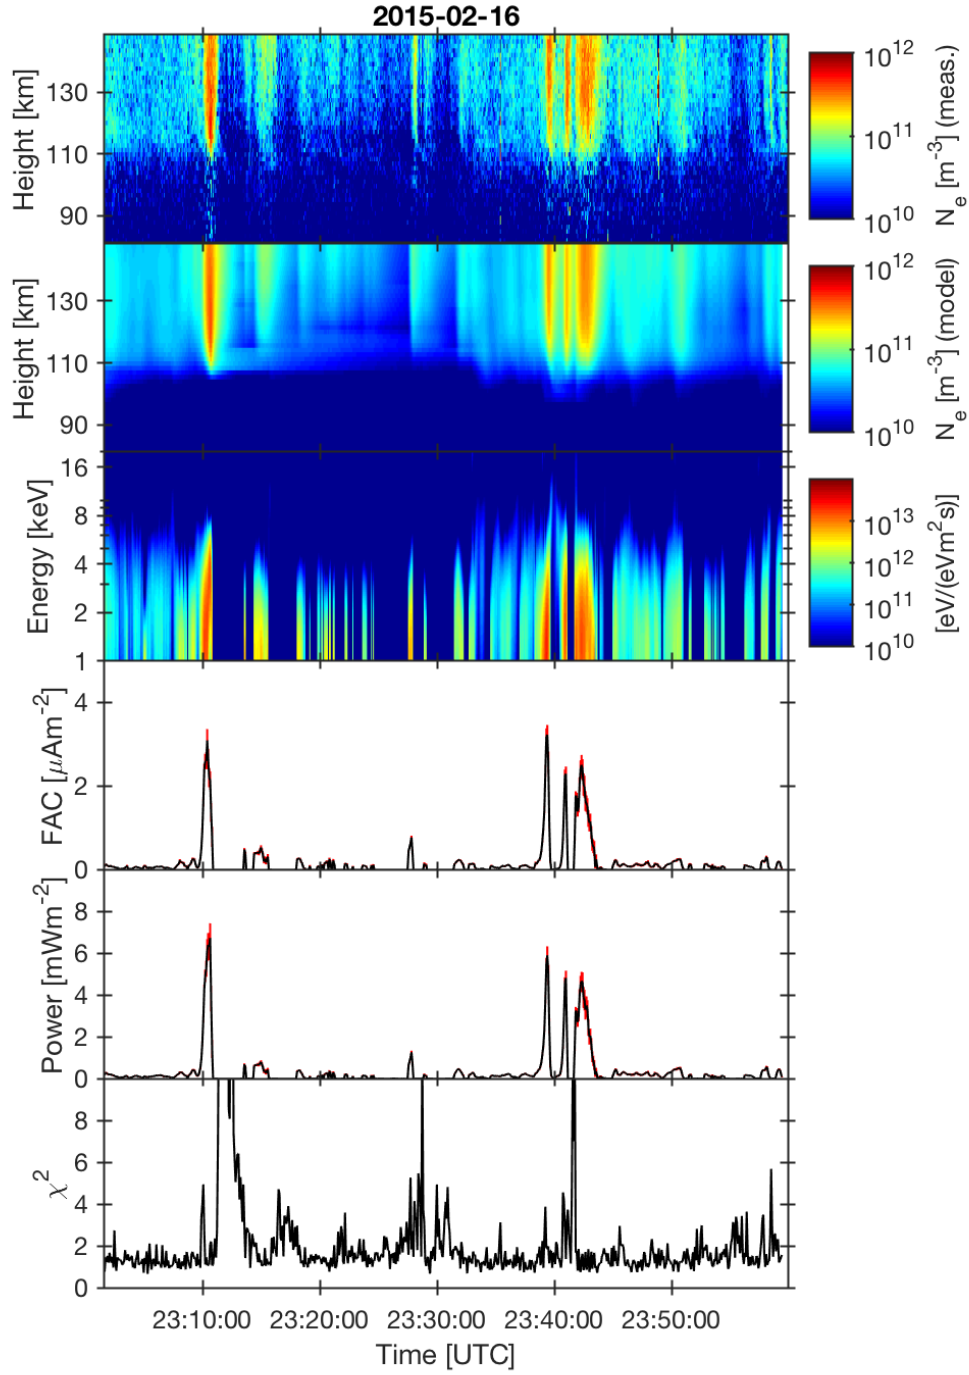

Figure 4.2: ELSPEC inversion results with the time dependent model and 5 s time resolution.

Figure 4.3: ELSPEC inversion results with the steady state model and 5 s time resolution.

Figure 4.4: ELSPEC inversion results with the steady state model and 60 s time resolution using only the standard GUISDAP fit results.

Appendix A

Command reference

This appendix lists the optional arguments of the functions `ElSpec` and `ElSpecPlot`.

A.1 ElSpec

All arguments to `ElSpec` are given using the standard MATLAB name-value pair notation, e.g. `ElSpec('inputdir','mydatadir')`, etc.

ppdir path to the raw electron densities.
Default: []
Example: `ElSpec('ppdir','1900-01-02_beata_5_rawNe@uhfa')`
NOTICE: either `ppdir` or `fitdir` must be defined.

fitdir path to the 'standard' GUISDAP fit results.
Default: []
Example: `ElSpec('fitdir','1900-01-02_beata_60@uhfa')`
NOTICE: either `ppdir` or `fitdir` must be defined. `fitdir` can be also a full path to a Madrigal hdf5 file with EISCAT data.

experiment Name of the EISCAT experiment. The argument is used for selecting correct input routine for the raw densities, and is written in the output filename.
Default: 'beata'
Example: `ElSpec('experiment','arc1')`

radar Name of the radar. The argument is used for selecting correct input routine for the raw densities, and is written in the output filename.

Default: 'uhf'
Example: `ElSpec('radar','esr')`

version   EISCAT experiment version. The argument is passed for the raw density input routines, but is currently not effective.
Default: 1

hmin   Lower altitude limit in kilometers. Must be from between 80 and 150 km.
Default: 80
Example: `ElSpec('hmin',95)`

hmax   Upper altitude limit in kilometers. Must be from between 80 and 150 km.
Default: 150
Example: `ElSpec('hmax',130)`

btime   Analysis start time as a vector [yyyy mm dd HH MM SS]. If not given, the analysis begins from the first available data point.
Default: []
Example: `ElSpec('btime',[1900 01 02 13 14 15])`

etime   Analysis end time as a vector [yyyy mm dd HH MM SS]. If not given, the analysis runs until end of data.
Default: []
Example: `ElSpec('etime',[1900 01 02 18 19 20])`

ionomodel   Ion production model, either `'Fang'` or `'Sergienko'`. The former is the model by *Fang et al.* (2010) and the latter is the model by *Sergienko and Ivanov* (1993). For both models, the neutral atmosphere is taken from the MATLAB aerospace toolbox implementation of NRLMSISE-00 model (*Picone et al.*, 2002).
Default: 'Fang'
Example: `ElSpec('ionomodel','Sergienko')`

recombmodel   Ion recombination model, the models differ in ion composition modeling and in effective recombination coefficient for NO^+ and O_2^+. The available options are:

Rees   Effective recombination coefficients from *Rees* (1989), ion composition from IRI.

ReesNO+   Effective recombination coefficients from *Rees* (1989), pure NO^+.

ReesO2+   Effective recombination coefficients from *Rees* (1989), pure O_2^+.

SheehanGr   Effective recombination coefficients for vibrational ground states from *Sheehan and St-Maurice* (2004), ion composition from IRI.

SheehanGrNO+   Effective recombination coefficients for vibrational ground states from *Sheehan and St-Maurice* (2004), pure NO^+.

SheehanGrO2+   Effective recombination coefficients for vibrational ground states from *Sheehan and St-Maurice* (2004), pure O_2^+.

SheehanEx   Effective recombination coefficients for vibrationally excited ions from *Sheehan and St-Maurice* (2004), ion composition from IRI.

delPozo1   Effective recombination coefficient as function of altitude, without ion composition. Equation (13) from *del Pozo et al.* (1997). The functional from is $\alpha_{eff} = 2.5 \cdot 10^{-12} \exp{(-0.0242h)} + 1.63 \cdot 10^5 \exp{(-0.524h)}$.

delPozo2   Effective recombination coefficient as function of altitude, without ion composition. A simpler equation from (page 1934 *del Pozo et al.*, 1997). $\alpha_{eff} = 2.5 \cdot 10^{-12} \exp{(-.0195h)}$.

Default: 'SheehanGr'
Example: `ElSpec('recombmodel','SheehanGrNO+')`
NOTICE: If `fitdir` is not defined, `recombmodel` has an effect on the electron temperature modeling. T_e is taken from IRI if `recombmodel` uses IRI, otherwise the temperature will be neutral temperature from MSIS.

integtype   Technique for integrating the electron continuity equation. `'integrate'`, `'endNe'` or `'equilibrium'`. `'integrate'` is the actual integration, `'endNe'` calculates electron density at end of a time step instead of the average over a time step. `'equilibrium'` assumes photochemical equilibrium, i.e. ignores the electron density time-derivative.
Default: 'integrate'
Example: `ElSpec('integtype','equilibrium')`
NOTICE: If `'integrate'` is selected, the electron density at end of each time step is calculated with the `'endNe'` option in a separate function call.

egrid   Energy grid points [eV].
Default: logspace(1,5,300)

Example: `ElSpec('egrid',logspace(log10(800),log10(8e4),200))`
NOTICE: ElSpec cannot invert energies much above 100 keV (altitudes below about 80 km), because the ion chemistry becomes too complicated, and because the polynomial in the spectrum models may lead to problematic oscillations at higher energies.

maxorder Maximum order of the polynomial model.
Default: 5
Example: `ElSpec('maxorder',10)`
NOTICE: the minimum order is always 1, we do not fit flat (constant) spectra.

plotres Logical, should the inversion results be plotted with `ElSpecPlot` during and after the inversion process.
Default: true
Example: `ElSpec('plotres',0)`

tres Time resolution for reading the raw electron density data in `ppdir`, either `'dump'` or `'best'`. `'dump'` integrates all raw density profiles from an EISCAT data dump in one profile, while `'best'` keeps the profiles separate. The final time resolution depends on the experiment, `'dump'` is 5 s for UHF beata and 4 s for UHF arc1. `'best'` is approximately 0.35 s for UHF beata and 0.44 s for UHF arc1.
Default: 'dump'
Example: `ElSpec('tres','best')`

emin Minimum energy used for estimating the field-aligned current and net energy flux [eV].
Default: 1000
Example: `ElSpec('emin',500)`
NOTICE: The lowest energies are not reliable, because the low energy electrons cause ionization mainly at altitudes above the 150 km upper boundary (and would be unreliable even if upper altitudes were included, due to convection and long recombination times). The lowest detectable energy varies a bit, along variations in density profile of the neutral atmosphere. The default 1 keV limit should be rather safe.

ieprior *A priori* differential number fluxes in the same energy and time grid that is used in the inversion. Use an empty matrix to run without a prior. This is

26

a remnant from the inversion development work, which was left in place, because it might still have some use. The original idea was to first run the inversion with the `'equilibrium'` integration, and use that result as a prior in the final analysis.

Default: []

Example: `ElSpec('ieprior',equilibriumresult.Ie)`

NOTICE: In the example above, `equilibriumresult` is an `ElSpec` output list from a similar inversion with `'integtype','equilibrium'`.

stdprior *A priori* standard deviations in the same energy and time grid that is used in the inversion. Use an empty matrix to run without a prior. See also `ieprior` above.

Default: []

Example: `ElSpec('ieprior',equilibriumresult.Ie)`

ninteg Number of time steps to integrate in each profile.

Default: 6

Example: `ElSpec('ninteg',1)`

NOTICE: Only the first time slice is included with a full weight. Weights for the others depend on the electron recombination time scale.

NOTICE: If `tres` is changed, `ninteg` should be changed accordingly.

NOTICE: To run the inversion without the adaptive integration, set `ninteg` to 1.

nstep Number of electron density time slices to proceed in each inversion step. Changing this might be reasonable in some cases if `tres` is `'best'`, but should not be touched typically.

Default: 1

Example: `ElSpec('nstep',2)`

saveiecov Logical, should the large number flux covariance matrices be saved? The matrices may be needed e.g. for recalculating the estimates of field-aligned current and net energy flux with different minimum energies `emin`. Correlations between nearby energy grid points are significant, and may be needed for some other purposes, too.

Default: false

Example: `ElSpec('saveiecov',1)`

FAdev   Maximum allowed deviation from field-aligned direction in degrees.
Default: 3
Example: `ElSpec('FAdev',5)`

bottomstdfail   Standard deviation given for model Ne in the lowest observed gate when the GUISDAP fit has failed [m^{-3}].
Default: 1e10
Example: `ElSpec('bottomstdfail',5e10)`

A.2   ElSpecPlot

`ElSpecPlot` has one required argument, `ElSpecOut`, which is an output list from `ElSpec`. In addition, it has one optional argument, `fignum`, which may be given immediately after `ElSpecOut` in the function call. The other optional parameters are given in the standard MATLAB name - value pair format.

ElSpecOut   An output list from `ElSpec`. This is a normal required argument.
Example: `out=ElSpec('fitdir','myFitDir'); ElSpecPlot(out)`
NOTICE: This is a normal MATLAB function argument, the call
`ElSpecPlot('ElSpecOut',out)` will not work.

fignum   Device number of the figure window, optional. If `fignum` is not given, a new figure window is created.
Example: `out=ElSpec('fitdir','myFitDir'); ElSpecPlot(out,2)`
NOTICE: Because `fignum` is not a MATLAB parameter but an optional argument, it must be given immediately after the `ElSpecOut` argument, and without its name.

hlim   Height limits in the electron density plot [km].
Default: Smallest and largest height found from `ElSpecOut`.
Example: `ElspecPlot(out,'hlim',[100 130])`

nelim   Limits of the electron density color scale [$\log_{10}(m^{-3})$].
Default: [10 12]
Example: `ElSpecPlot(out,'nelim',[9 11])`

ielim   Limits for differential number flux color scale [$\log_{10}((eVm^2s)^{-1})$].
Default: [6 10]
Example: `ElSpecPlot(out,'ielim',[7 11])`

NOTICE: The differential number flux is not plotted by default, see `'fluxtype'`.

ieelim   Limits for differential energy flux color scale [$\log_{10}(\text{eV}(\text{eVm}^2\text{s})^{-1})$].
         Default: [10 14]
         Example: ElSpecPlot(out,'ieelim',[9 12])

elim   Energy axis limits in the flux plots [keV].
       Default: [1 100]
       Example: ElSpecPlot(out,'elim',[1 40])

faclim   Current axis limits in the plot of field-aligned current [μAm^{-2}].
         Default: [0 10]
         Example: ElSpecPlot(out,'faclim',[0 30])

plim   Energy axis limits in the plot of net energy flux [mWm^{-2}].
       Default: [0 50]
       Example: ElSpecPlot(out,'plim',[0 200])

chisqrlim   Axis limits for the χ^2 plot.
            Default: [0 10]
            Example: ElSpecPlot(out,'chisqrlim',[0 50])

btime   Start time as a vector [yyyy mm dd HH MM SS]. If not given, the plot begins from the first data point in ElSpecOut.
        Default: []
        Example: ElSpecPlot(out,'btime',[1900 01 02 13 14 15])

etime   End time as a vector [yyyy mm dd HH MM SS]. If not given, the plot ends at the last data point in ElSpecOut.
        Default: []
        Example: ElSpecPlot(out,'etime',[1900 01 02 18 19 20])

fluxtype   Type of the differential number flux plot 'number', 'energy' or 'both'. 'number' is the differential number flux, 'energy' is the differential

energy flux, and `'both'` plots both fluxes. If `'both'` is selected, the net power flux plot is omitted.
Default: 'energy'
Example: `ElSpecPlot(out,'fluxtype','number')`

neplot
Type of the electron density plot. `'log'` uses a logarithmic density scale, `'linear'` plots in linear scale.
Default: 'log'
Example: `ElSpecPlot(out,'neplot','linear')`
NOTICE: `nelim` is given in logarithmic scale even if `'linear'` is selected.

emin
Minimum energy included in field-aligned current and net power flux estimates [eV]. If the value is different from `ElSpecOut.emin`, the estimates of field-aligned current and net power flux are recalculated.
Default: 1000
Example: `ElSpecPlot(out,'emin',500)`
NOTICE: Error estimates of FAC and net power flux can be recalculated only if the full covariance matrix of the number flux is available (`saveiecov` is `true`) in `ElSpec`. If the covariance matrix is not available, the estimates are plotted without error bars.

fontsize
Font size in axis labels.
Default: 8
Example: `ElSpecPlot(out,'fontsize',10)`

cutgaps
Logical, should white space be plotted on obvious data gaps?
Default: true
Example: `ElSpecPlot(out,'cutgaps',false)`

Appendix B

Output file structure

The ELSPEC output files contain a MATLAB structure `ElSpecOut`. The structure contains a copy of all input arguments, bot those explicitly defined and those with the default values. In addition, following fit results are included.

Nflux Differential number flux $[(\text{eVm}^2\text{s})^{-1}]$

Ie Differential number flux (copy of Nflux, for backward compatibility) $[(\text{eVm}^2\text{s})^{-1}]$

IeStd Standard deviation of differential number flux $[(\text{eVm}^2\text{s})^{-1}]$

IeCov Full covariance matrices of the differential number flux $[(\text{eVm}^2\text{s})^{-2}]$

FAC Field-aligned current carried by the precipitating electrons $[\text{Am}^{-2}]$

FACstd Standard deviation of FAC $[\text{Am}^{-2}]$

Eflux Differential energy flux $[\text{eV}(\text{eVm}^2\text{s})^{-1}]$

Pe Differential energy flux (for backward compatibility) $[\text{eV}(\text{eVm}^2\text{s})^{-1}]$

PeStd Standard deviation of differential energy flux $[\text{eV}(\text{eVm}^2\text{s})^{-1}]$

E0 Peak energy (the energy where Eflux reaches its maximum) [eV]

q Ion production rate $\text{m}^{-3}\text{s}^{-1}$

E Energy bin boundaries [eV]

Ec Centre points of energy bins [eV]

dE Energy bin widths [eV]

31

ts	time step start times [unix time]
te	time step end times [unix time]
dt	time step durations [s]
h	altitude bin centre points [km]
polycoefs	fitted polynomial coefficients
polycoefsCovar	Covariances of the polynomial coefficients
AICc	Akaike information criterion values
best_order	Best polynomial order based on AICc
output	outputs from the fminsearch function
exitflag	exit flag of fminsearch
chisqr	normalized summed square of residuals
A	The ion production rate matrix A (only one example stored)
alpha	effective recombination rates [m^3s^-1]
loc	Radar location (lat, lon) [degrees]
azel	Radar azimuth and elevation [degrees]
pp	raw electron density (or fitted if `ppdir` is not defined) [m^{-3}]
ppstd	standard deviations of raw densities [m^{-3}]
ne	Modelled electron density measurements [m^{-3}]
neEnd	Modelled electron densities at end of each time step [m^{-3}]
neEndCov	Covariance matrices of neEnd [m^{-6}]
neEndStd	Standard deviations of neEnd [m^{-3}]
par	Array of measured plasma parameters
parstd	Standard deviations of par
iri	Array of model densities and temperatures
I	Magnetic inclination

GNU General Public License

```
                 GNU GENERAL PUBLIC LICENSE
                    Version 2, June 1991

 Copyright (C) 1989, 1991 Free Software Foundation, Inc.,
 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA
 Everyone is permitted to copy and distribute verbatim copies
 of this license document, but changing it is not allowed.

                         Preamble

   The licenses for most software are designed to take away your
freedom to share and change it.  By contrast, the GNU General Public
License is intended to guarantee your freedom to share and change free
software--to make sure the software is free for all its users.
This
General Public License applies to most of the Free Software
Foundation's software and to any other program whose authors commit to
using it.  (Some other Free Software Foundation software is covered by
the GNU Lesser General Public License instead.)
You can apply it to
your programs, too.

   When we speak of free software, we are referring to freedom, not
price.  Our General Public Licenses are designed to make sure that you
have the freedom to distribute copies of free software (and charge for
this service if you wish), that you receive source code or can get it
if you want it, that you can change the software or use pieces of it
in new free programs; and that you know you can do these things.

   To protect your rights, we need to make restrictions that forbid
anyone to deny you these rights or to ask you to surrender the rights.
These restrictions translate to certain responsibilities for you if you
```

distribute copies of the software, or if you modify it.

   For example, if you distribute copies of such a program, whether
gratis or for a fee, you must give the recipients all the rights that
you have. You must make sure that they, too, receive or can get the
source code. And you must show them these terms so they know their
rights.

   We protect your rights with two steps: (1) copyright the software, and
(2) offer you this license which gives you legal permission to copy,
distribute and/or modify the software.

   Also, for each author's protection and ours, we want to make certain
that everyone understands that there is no warranty for this free
software. If the software is modified by someone else and passed on, we
want its recipients to know that what they have is not the original, so
that any problems introduced by others will not reflect on the original
authors' reputations.

   Finally, any free program is threatened constantly by software
patents. We wish to avoid the danger that redistributors of a free
program will individually obtain patent licenses, in effect making the
program proprietary. To prevent this, we have made it clear that any
patent must be licensed for everyone's free use or not licensed at all.

   The precise terms and conditions for copying, distribution and
modification follow.

                    GNU GENERAL PUBLIC LICENSE
   TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

   0. This License applies to any program or other work which contains
a notice placed by the copyright holder saying it may be distributed
under the terms of this General Public License.
The "Program", below,
refers to any such program or work, and a "work based on the Program"
means either the Program or any derivative work under copyright law:
that is to say, a work containing the Program or a portion of it,
either verbatim or with modifications and/or translated into another
language. (Hereinafter, translation is included without limitation in
the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not
covered by this License; they are outside its scope. The act of
running the Program is not restricted, and the output from the Program
is covered only if its contents constitute a work based on the
Program (independent of having been made by running the Program).
Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's
source code as you receive it, in any medium, provided that you
conspicuously and appropriately publish on each copy an appropriate
copyright notice and disclaimer of warranty; keep intact all the
notices that refer to this License and to the absence of any warranty;
and give any other recipients of the Program a copy of this License
along with the Program.

You may charge a fee for the physical act of transferring a copy, and
you may at your option offer warranty protection in exchange for a fee.

  2. You may modify your copy or copies of the Program or any portion
of it, thus forming a work based on the Program, and copy and
distribute such modifications or work under the terms of Section 1
above, provided that you also meet all of these conditions:

    a) You must cause the modified files to carry prominent notices
    stating that you changed the files and the date of any change.

    b) You must cause any work that you distribute or publish, that in
    whole or in part contains or is derived from the Program or any
    part thereof, to be licensed as a whole at no charge to all third
    parties under the terms of this License.

    c) If the modified program normally reads commands interactively
    when run, you must cause it, when started running for such
    interactive use in the most ordinary way, to print or display an
    announcement including an appropriate copyright notice and a
    notice that there is no warranty (or else, saying that you provide
    a warranty) and that users may redistribute the program under
    these conditions, and telling the user how to view a copy of this
    License. (Exception: if the Program itself is interactive but
    does not normally print such an announcement, your work based on
    the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If
identifiable sections of that work are not derived from the Program,
and can be reasonably considered independent and separate works in
themselves, then this License, and its terms, do not apply to those
sections when you distribute them as separate works.
But when you
distribute the same sections as part of a whole which is a work based
on the Program, the distribution of the whole must be on the terms of
this License, whose permissions for other licensees extend to the
entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest
your rights to work written entirely by you; rather, the intent is to
exercise the right to control the distribution of derivative or

collective works based on the Program.

In addition, mere aggregation of another work not based on the Program
with the Program (or with a work based on the Program) on a volume of
a storage or distribution medium does not bring the other work under
the scope of this License.

  3. You may copy and distribute the Program (or a work based on it,
under Section 2) in object code or executable form under the terms of
Sections 1 and 2 above provided that you also do one of the following:

    a) Accompany it with the complete corresponding machine-readable
    source code, which must be distributed under the terms of Sections
    1 and 2 above on a medium customarily used for software interchange; or,

    b) Accompany it with a written offer, valid for at least three
    years, to give any third party, for a charge no more than your
    cost of physically performing source distribution, a complete
    machine-readable copy of the corresponding source code, to be
    distributed under the terms of Sections 1 and 2 above on a medium
    customarily used for software interchange; or,

    c) Accompany it with the information you received as to the offer
    to distribute corresponding source code.
(This alternative is
    allowed only for noncommercial distribution and only if you
    received the program in object code or executable form with such
    an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for
making modifications to it. For an executable work, complete source
code means all the source code for all modules it contains, plus any
associated interface definition files, plus the scripts used to
control compilation and installation of the executable.
However, as a
special exception, the source code distributed need not include
anything that is normally distributed (in either source or binary
form) with the major components (compiler, kernel, and so on) of the
operating system on which the executable runs, unless that component
itself accompanies the executable.

If distribution of executable or object code is made by offering
access to copy from a designated place, then offering equivalent
access to copy the source code from the same place counts as
distribution of the source code, even though third parties are not
compelled to copy the source along with the object code.

  4. You may not copy, modify, sublicense, or distribute the Program
except as expressly provided under this License. Any attempt

otherwise to copy, modify, sublicense or distribute the Program is
void, and will automatically terminate your rights under this License.
However, parties who have received copies, or rights, from you under
this License will not have their licenses terminated so long as such
parties remain in full compliance.

  5. You are not required to accept this License, since you have not
signed it. However, nothing else grants you permission to modify or
distribute the Program or its derivative works.
These actions are
prohibited by law if you do not accept this License.
Therefore, by
modifying or distributing the Program (or any work based on the
Program), you indicate your acceptance of this License to do so, and
all its terms and conditions for copying, distributing or modifying
the Program or works based on it.

  6. Each time you redistribute the Program (or any work based on the
Program), the recipient automatically receives a license from the
original licensor to copy, distribute or modify the Program subject to
these terms and conditions. You may not impose any further
restrictions on the recipients' exercise of the rights granted herein.
You are not responsible for enforcing compliance by third parties to
this License.

  7. If, as a consequence of a court judgment or allegation of patent
infringement or for any other reason (not limited to patent issues),
conditions are imposed on you (whether by court order, agreement or
otherwise) that contradict the conditions of this License, they do not
excuse you from the conditions of this License. If you cannot
distribute so as to satisfy simultaneously your obligations under this
License and any other pertinent obligations, then as a consequence you
may not distribute the Program at all. For example, if a patent
license would not permit royalty-free redistribution of the Program by
all those who receive copies directly or indirectly through you, then
the only way you could satisfy both it and this License would be to
refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under
any particular circumstance, the balance of the section is intended to
apply and the section as a whole is intended to apply in other
circumstances.

It is not the purpose of this section to induce you to infringe any
patents or other property right claims or to contest validity of any
such claims; this section has the sole purpose of protecting the
integrity of the free software distribution system, which is
implemented by public license practices. Many people have made
generous contributions to the wide range of software distributed

through that system in reliance on consistent application of that
system; it is up to the author/donor to decide if he or she is willing
to distribute software through any other system and a licensee cannot
impose that choice.

This section is intended to make thoroughly clear what is believed to
be a consequence of the rest of this License.

   8. If the distribution and/or use of the Program is restricted in
certain countries either by patents or by copyrighted interfaces, the
original copyright holder who places the Program under this License
may add an explicit geographical distribution limitation excluding
those countries, so that distribution is permitted only in or among
countries not thus excluded. In such case, this License incorporates
the limitation as if written in the body of this License.

   9. The Free Software Foundation may publish revised and/or new versions
of the General Public License from time to time.
Such new versions will
be similar in spirit to the present version, but may differ in detail to
address new problems or concerns.

Each version is given a distinguishing version number.
If the Program
specifies a version number of this License which applies to it and "any
later version", you have the option of following the terms and conditions
either of that version or of any later version published by the Free
Software Foundation. If the Program does not specify a version number of
this License, you may choose any version ever published by the Free Software
Foundation.

   10. If you wish to incorporate parts of the Program into other free
programs whose distribution conditions are different, write to the author
to ask for permission. For software which is copyrighted by the Free
Software Foundation, write to the Free Software Foundation; we sometimes
make exceptions for this. Our decision will be guided by the two goals
of preserving the free status of all derivatives of our free software and
of promoting the sharing and reuse of software generally.

                            NO WARRANTY

   11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY
FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW.
EXCEPT WHEN
OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES
PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED
OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF
MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.
THE ENTIRE RISK AS

TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU.
SHOULD THE
PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING,
REPAIR OR CORRECTION.

   12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING
WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR
REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES,
INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING
OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED
TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY
YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER
PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE
POSSIBILITY OF SUCH DAMAGES.

                    END OF TERMS AND CONDITIONS

              How to Apply These Terms to Your New Programs

   If you develop a new program, and you want it to be of the greatest
possible use to the public, the best way to achieve this is to make it
free software which everyone can redistribute and change under these terms.

   To do so, attach the following notices to the program.
It is safest
to attach them to the start of each source file to most effectively
convey the exclusion of warranty; and each file should have at least
the "copyright" line and a pointer to where the full notice is found.

    <one line to give the program's name and a brief idea of what it does.>
    Copyright (C) <year> <name of author>

    This program is free software; you can redistribute it and/or modify
    it under the terms of the GNU General Public License as published by
    the Free Software Foundation; either version 2 of the License, or
    (at your option) any later version.

    This program is distributed in the hope that it will be useful,
    but WITHOUT ANY WARRANTY; without even the implied warranty of
    MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.
See the
    GNU General Public License for more details.

    You should have received a copy of the GNU General Public License along
    with this program; if not, write to the Free Software Foundation, Inc.,
    51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this
when it starts in an interactive mode:

    Gnomovision version 69, Copyright (C) year name of author
    Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type 'show w'.
    This is free software, and you are welcome to redistribute it
    under certain conditions; type 'show c' for details.

The hypothetical commands 'show w' and 'show c' should show the appropriate
parts of the General Public License. Of course, the commands you use may
be called something other than 'show w' and 'show c'; they could even be
mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your
school, if any, to sign a "copyright disclaimer" for the program, if
necessary. Here is a sample; alter the names:

  Yoyodyne, Inc., hereby disclaims all copyright interest in the program
  'Gnomovision' (which makes passes at compilers) written by James Hacker.

  <signature of Ty Coon>, 1 April 1989
  Ty Coon, President of Vice

This General Public License does not permit incorporating your program into
proprietary programs. If your program is a subroutine library, you may
consider it more useful to permit linking proprietary applications with the
library. If this is what you want to do, use the GNU Lesser General
Public License instead of this License.
